

Cybersecurity Incident Report:

Network Traffic Analysis

Part 1: Provide a summary of the problem found in the DNS and ICMP traffic log.

The UDP protocol reveals that: The UDP protocol indicates that the default port is unreachable, meaning that no service is listening on or responding through that port.

This is based on the results of the network analysis, which show that the ICMP echo reply returned the error message: UDP port 53 Unreachable

The port noted in the error message is used for: DNS server

The most likely issue is: the DNS service is not running or is not listening on UDP port 53. Alternatively, a firewall may be blocking DNS traffic.

Part 2: Explain your analysis of the data and provide at least one cause of the incident.

The incident occurred around midday, when multiple customers reported being unable to access the website yummyrecipesforme.com.

Following a network analysis using packet sniffing tools and logs, we identified that UDP port 53, which is responsible for DNS queries, appears to be related to the issue. The captured traffic showed "UDP Port 53 Unreachable", indicating that DNS requests were not being processed successfully.

At this time, we are working to resolve the issue and are investigating several possible causes. The most likely explanations are that the DNS service is not running or listening on UDP port 53, or that a firewall is blocking DNS traffic. We also believe that a firewall outage or misconfiguration may have contributed to the incident.

Current log analysis does not indicate evidence of malicious activity or dos attacks. However, to ensure the security of the environment, a thorough investigation will be conducted by the security team. This review will help confirm the root cause of the incident and provide assurance to the organization that no breach or attack was involved
